NPTEL Course on Principles of Compiler Design

- Introduction
- Attribute grammars
- Attributed translation grammars
- Semantic analysis with attributed translation grammars

◆□▶ ◆□▶ ★ □▶ ★ □▶ → □ → の Q ()

Compiler Overview

Semantic Analysis

- Semantic consistency that cannot be handled at the parsing stage is handled here
- Parsers cannot handle context-sensitive features of programming languages
- These are *static semantics* of programming languages and can be checked by the semantic analyzer
 - Variables are declared before use
 - Types match on both sides of assignments
 - Parameter types and number match in declaration and use
- Compilers can only generate code to check dynamic semantics of programming languages at runtime
 - whether an overflow will occur during an aritmetic operation
 - whether array limits will be crossed during execution
 - whether recursion will cross stack limits
 - whether heap memory will be insufficient

イロン 不良 とくほう 不良 とうほ

Static Semantics

```
int dot_prod(int x[], int y[]){
    int d, i; d = 0;
    for (i=0; i<10; i++) d += x[i]*y[i];
    return d;
}
main(){
    int p; int a[10], b[10];
    p = dot_prod(a,b);
}</pre>
```

Samples of static semantic checks in main

- Types of *p* and return type of *dot_prod* match
- Number and type of the parameters of *dot_prod* are the same in both its declaration and use
- p is declared before use, same for a and b

Static Semantics: Errors given by gcc Compiler

```
int dot_product(int a[], int b[]) {...}
```

```
1 main(){int a[10]={1,2,3,4,5,6,7,8,9,10};
```

```
2 int b[10]={1,2,3,4,5,6,7,8,9,10};
```

```
3 printf("%d", dot_product(b));
```

```
4 printf("%d", dot_product(a,b,a));
```

```
5 int p[10]; p=dotproduct(a,b); printf("%d",p);}
```

In function `main':
error in 3: too few arguments to fn `dot_product'
error in 4: too many arguments to fn `dot_product'
error in 5: incompatible types in assignment
warning in 5: format `%d' expects type `int', but
argument 2 has type `int *'

◆□▶ ◆□▶ ◆ 三▶ ◆ 三▶ ・ 三 ・ のへぐ

Static Semantics

```
int dot_prod(int x[], int y[]){
    int d, i; d = 0;
    for (i=0; i<10; i++) d += x[i]*y[i];
    return d;
}
main(){
    int p; int a[10], b[10];
    p = dot_prod(a,b);
}</pre>
```

Samples of static semantic checks in dot_prod

- *d* and *i* are declared before use
- Type of *d* matches the return type of *dot_prod*
- Type of *d* matches the result type of "*"
- Elements of arrays x and y are compatible with "*"

Dynamic Semantics

```
int dot_prod(int x[], int y[]){
    int d, i; d = 0;
    for (i=0; i<10; i++) d += x[i]*y[i];
    return d;
}
main(){
    int p; int a[10], b[10];
    p = dot_prod(a,b);
}</pre>
```

Samples of dynamic semantic checks in *dot_prod*

- Value of *i* does not exceed the declared range of arrays x and y (both lower and upper)
- There are no overflows during the operations of "*" and "+" in d += x[i]*y[i]

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ● ● ○ ○ ○

```
int fact(int n) {
    if (n==0) return 1;
    else return (n*fact(n-1));
}
main(){int p; p = fact(10); }
```

Samples of dynamic semantic checks in fact

- Program stack does not overflow due to recursion
- There is no overflow due to "*" in n*fact (n-1)

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

Semantic Analysis

- Type information is stored in the symbol table or the syntax tree
 - Types of variables, function parameters, array dimensions, etc.
 - Used not only for semantic validation but also for subsequent phases of compilation
- If declarations need not appear before use (as in C++), semantic analysis needs more than one pass
- Static semantics of PL can be specified using attribute grammars
- Semantic analyzers can be generated semi-automatically from attribute grammars
- Attribute grammars are extensions of context-free grammars

Attribute Grammars

- Let G = (N, T, P, S) be a CFG and let $V = N \cup T$.
- Every symbol X of V has associated with it a set of *attributes* (denoted by X.a, X.b, etc.)
- Two types of attributes: *inherited* (denoted by *AI*(*X*))and *synthesized* (denoted by *AS*(*X*))
- Each attribute takes values from a specified domain (finite or infinite), which is its *type*
 - Typical domains of attributes are, integers, reals, characters, strings, booleans, structures, etc.
 - New domains can be constructed from given domains by mathematical operations such as cross product, map, etc.
 - *array*: a map, $\mathcal{N} \to \mathcal{D}$, where, \mathcal{N} and \mathcal{D} are domains of natural numbers and the given objects, respectively
 - structure: a cross-product, A₁ × A₂ × ... × A_n, where n is the number of fields in the structure, and A_i is the domain of the ith field

・ロト ・ 同ト ・ ヨト ・ ヨト … ヨ

Attribute Computation Rules

- A production *p* ∈ *P* has a set of attribute computation rules (functions)
- Rules are provided for the computation of
 - Synthesized attributes of the LHS non-terminal of p
 - Inherited attributes of the RHS non-terminals of p
- These rules can use attributes of symbols from the production *p* only
 - Rules are strictly local to the production *p* (no side effects)
- Restrictions on the rules define different types of attribute grammars
 - L-attribute grammars, S-attribute grammars, ordered attribute grammars, absolutely non-circular attribute grammars, etc.

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ● □ ● ● ● ●

Synthesized and Inherited Attributes

- An attribute cannot be both synthesized and inherited, but a symbol can have both types of attributes
- Attributes of symbols are evaluated over a parse tree by making passes over the parse tree
- Synthesized attributes are computed in a bottom-up fashion from the leaves upwards
 - Always synthesized from the attribute values of the children of the node
 - Leaf nodes (terminals) have synthesized attributes initialized by the lexical analyzer and cannot be modified
 - An AG with only synthesized attributes is an *S*-attributed grammar (SAG)
 - YACC permits only SAGs
- Inherited attributes flow down from the parent or siblings to the node in question

<ロ> (四) (四) (三) (三) (三) (三)

- The following CFG $S \rightarrow A B C, A \rightarrow aA \mid a, B \rightarrow bB \mid b, C \rightarrow cC \mid c$ generates: $L(G) = \{a^m b^n c^p \mid m, n, p \ge 1\}$
- We define an AG (attribute grammar) based on this CFG to generate L = {aⁿbⁿcⁿ | n ≥ 1}
- All the non-terminals will have only synthesized attributes

•
$$AS(S) = \{equal \uparrow: \{T, F\}\}$$

• $AS(A) = AS(B) = AS(C) = \{count \uparrow: integer\}$

・ロト ・ 理 ト ・ ヨ ト ・

・ロト ・ 理 ト ・ ヨ ト ・

・ロト ・ 理 ト ・ ヨ ト ・

・ロト ・ 理 ト ・ ヨ ト ・

- Let T be a parse tree generated by the CFG of an AG, G.
- The attribute dependence graph (dependence graph for short) for T is the directed graph, DG(T) = (V, E), where

 $V = \{b|b \text{ is an attribute instance of some tree node}\}$, and

 $E = \{(b, c) | b, c \in V, b \text{ and } c \text{ are attributes of grammar}$ symbols in the same production p of B, and the value of b is used for computing the value of c in an attribute computation rule associated with production p}

- An AG *G* is *non-circular*, iff for all trees *T* derived from *G*, DG(T) is acyclic
 - Non-circularity is very expensive to determine (exponential in the size of the grammar)
 - Therefore, our interest will be in subclasses of AGs whose non-circularity can be determined efficiently
- Assigning consistent values to the attribute instances in DG(T) is attribute evaluation

・ロト ・ 同ト ・ ヨト ・ ヨト … ヨ

- Construct the parse tree
- Construct the dependence graph
- Perform topological sort on the dependence graph and obtain an evaluation order
- Evaluate attributes according to this order using the corresponding attribute evaluation rules attached to the respective productions
- Multiple attributes at a node in the *parse tree* may result in that node to be visited multiple number of times
 - Each visit resulting in the evaluation of at least one attribute

Input: A parse tree T with unevaluated attribute instances **Output:** T with consistent attribute values

{ Let
$$(V, E) = DG(T)$$
;

Let $W = \{b \mid b \in V \& indegree(b) = 0\};$

while $W \neq \phi$ do

{ remove some *b* from *W*;

```
for all (b, c) \in E do
```

```
{ indegree(c) := indegree(c) - 1;
```

```
if indegree(c) = 0 then W := W \cup \{c\};
```

Dependence Graph for Example 1

1,2,3,4,5,6,7 and 2,3,6,5,1,4,7 are two possible evaluation orders. 1,4,2,5,3,6,7 can be used with LR-parsing. The right-most derivation is below (its reverse is LR-parsing order)

S => ABC => ABcC => ABcc => AbBcc => Abbcc => aAbbcc => aabbcc

1. A.count = 1 {A
$$\rightarrow$$
 a, {A.count := 1}}
4. A.count = 2 {A₁ \rightarrow aA₂, {A₁.count := A₂.count + 1}}
2. B.count = 1 {B \rightarrow b, {B.count := 1}}
5. B.count = 2 {B₁ \rightarrow bB₂, {B₁.count := B₂.count + 1}}
3. C.count = 1 {C \rightarrow c, {C.count :=1}}
6. C.count = 2 {C₁ \rightarrow cC₂, {C₁.count := C₂.count + 1}}
7. S.equal = 1 {S \rightarrow ABC, {Sequal := if A.count = B.count &
B.count = C.count then T else F}

Attribute Grammar - Example 2

 AG for the evaluation of a real number from its bit-string representation
 Example: 110.101 = 6.625

•
$$N \rightarrow L.R, L \rightarrow BL \mid B, R \rightarrow BR \mid B, B \rightarrow 0 \mid 1$$

•
$$AS(N) = AS(R) = AS(B) = \{value \uparrow: real\},$$

 $AS(L) = \{length \uparrow: integer, value \uparrow: real\}$
• $N \rightarrow L.R \{N.value \uparrow:= L.value \uparrow + R.value \uparrow\}$
• $L \rightarrow B \{L.value \uparrow:= B.value \uparrow; L.length \uparrow:= 1\}$
• $L_1 \rightarrow BL_2 \{L_1.length \uparrow:= L_2.length \uparrow + 1;$
 $L_1.value \uparrow:= B.value \uparrow *2^{L_2.length\uparrow} + L_2.value \uparrow\}$
• $R \rightarrow B \{R.value \uparrow:= B.value \uparrow /2\}$
• $R_1 \rightarrow BR_2 \{R_1.value \uparrow:= (B.value \uparrow + R_2.value \uparrow)/2\}$
• $B \rightarrow 0 \{B.value \uparrow:= 0\}$
• $B \rightarrow 1 \{B.value \uparrow:= 1\}$
